### 1. INTRODUCTION

The research described in this report is part of a continuing program (Ref. 1 and 2) of investigation of the processes involved in acoustic and nonacoustic low-frequency combustion instability behavior of solid-propellant rocket motors and in various aspects of steady-state combustion believed to be related to combustion instability. Accompanying work on the deflagration of ammonium perchlorate has been recently reported (Ref. 3).

This report is divided into three parts. The first part gives the strand burning rates of the various propellants used in the combustion instability studies, compares the results with the granular diffusion flame theory, and points out the need for a more thorough examination of the burning-rate-pressure relationship assumed for the mathematical models of combustion instability. The second part presents additional experimental data on nonacoustic instability for propellants using a carboxy-terminated polybutadiene binder; these data like those obtained from polyurethane binder propellants (Ref. 1 and 2) also deviate from the one-dimensional theory. The third part of the report presents an extended mathematical description of nonisentropic behavior in the T-burner and compares experimental observations of the gas motion and temperature with theoretical predictions.

### 2. STEADY-STATE COMBUSTION

### 2.1 INTRODUCTION

Knowledge of the pressure dependence of the burning rate of a solid propellant is necessary in order to make predictions of the combustion stability using currently available theories. To obtain this information for the propellants being used in the combustion instability studies and to perhaps gain further insight into the steady-state-combustion processes of composite propellants, a detailed determination of the strand burning rate of these propellants was made. This section presents the data for two classes of propellants: a series of ammonium perchlorate (AP) and polyurethane (PU) propellants, and a series composed of AP and carboxy-terminated polybutadiene (CTPB). The formulations tested are given in Table 2.1.

### 2.2 EXPERIMENTAL TECHNIQUES

The samples used were 1/4- by 1/4- by 2-inch strands and were mounted in the combustion bomb (Ref. 1) and ignited by a 10-mil heated Nichrome wire. Two different systems were used to detect the regressing surface: the conventional fuze wire approach (Fig. 2.1a) and a technique, developed at this Center, which optically detects the burning surface (Fig. 2.1b).

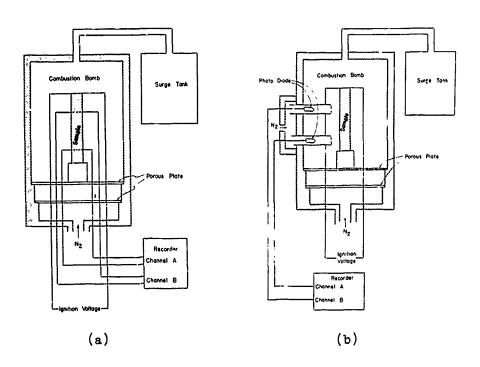

FIG. 2.1. Burning Rate Apparatus. (a) Conventional strand burner, (b) NWC photodiode device.

This new apparatus utilizes photodiodes placed behind slit apertures to detect light emission as the burning surface passes the aperture. This technique has the advantages of (1) presenting no discontinuities (fuze wires, thermocouples, etc.) to the combustion front, (2) requiring no inhibiting of the samples, and (3) being able to detect a burning surface which is not normal to the strand axis. Data obtained from these two methods are in good agreement; further comparison with the rate calculated from high speed cinephotomicrography indicates that the photodiode method gives a rate slightly more consistent with that abtained from the motion pictures.

### 2.3 RESULTS AND DISCUSSION

The burning-rate curves are presented for the PU propellants (Fig. 2.2-2.11) and the CTPB propellants (Fig. 2.12-2.17). Each data point represents one burning rate test. In looking first at the combined plot (Fig. 2.2) which gives most of the burning rates for the polyurethanes, several features are discernible. The first observation is that many of these propellants extinguish at high pressures. The reason for this extinguishment is thought to be due to two conditions: (1) the position of the oxidizer particles relative to the binder surface as a

<sup>&</sup>lt;sup>1</sup>The approximate upper deflagration limit is denoted by x in Fig. 2.2.

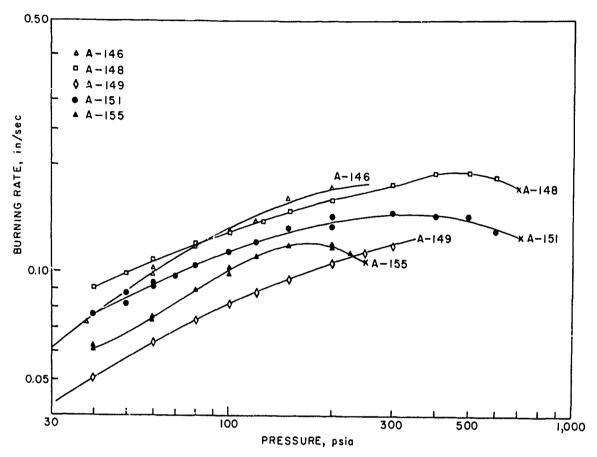

FIG. 2.2. Burning Rate Curves for Polyurethane-Ammonium Perchlorate Propellants.

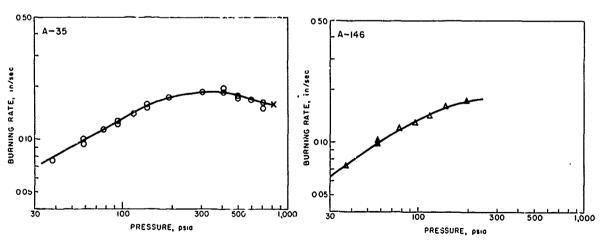

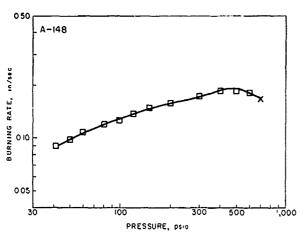

FIG. 2.3. Burning Rate Curve for Propellant A-35.

FIG. 2.4. Burning Rate Curve for Propellant A-146.

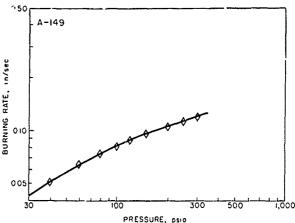

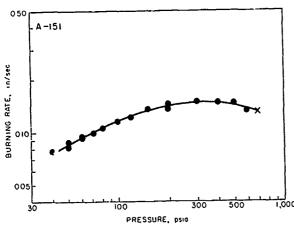

FIG. 2.5. Burning Rate Curve for Propellant A-148.

FIG. 2.6. Burning Rate Curve for Propellant A-149.

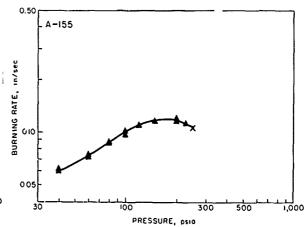

FIG. 2.7. Burning Rate Curve for Propellant A-151.

FIG. 2.8. Burning Rate Curve for Propellant A-155.

function of pressure, and (2) the meltability of the binder. It has been observed (Ref. 4) that at low pressures (p < 600 psia) the regression rate of the binder was higher than the oxidizer particles but at higher pressures (p > 800 psi) the opposite was found to be true. Therefore, an extinguishment mechanism may be formulated to account for the high pressure extinguishment of polyurethane propellants; at low pressures the oxidizer is above the binder so that the meltability of the binder has little effect but when the regression rate of binder and cxidizer are about equal, the molten binder may wet and cover the oxidizer particles. Such behavior could cause extinguishment and this hypothesis is currently being investigated using cinephotomicrography and scanning electron microscope (SEM) examination of quenched samples.

The property of the state of the

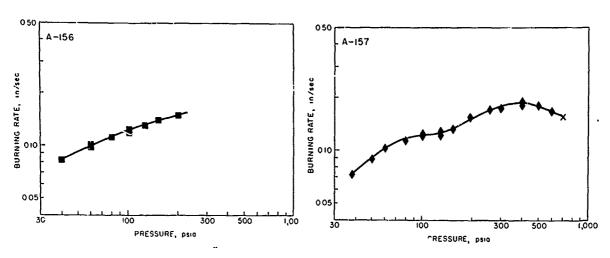

FIG. 2.9. Burning Rate Curve for Propellanc A-156.

FIG. 2.10. Burning Rate Curve for Propellant A-157.

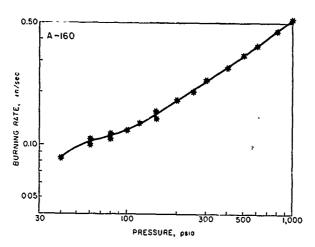

FIG. 2.11. Burning Rate Curve for Propellant A-160.

The trend of higher burning rates for propellants having smaller oxidizer particles (Ref. 5) is apparent when the curves for propellants A-146 (15- and 90-micron AP particles) and A-148 (15- and 200-micron AP particles) are compared with the A-149 (90- and 600-micron AP) and A-155 (45- and 400-micron AP) propellants. The study of quenched propellant samples using the SEM may suggest the mechanism for this well recognized observation.

The data for propellant A=160 (Fig. 2.11) show that often the plateau and mesa-burning-rate characteristics can be altered by additives as well as by AP-particle-size changes.

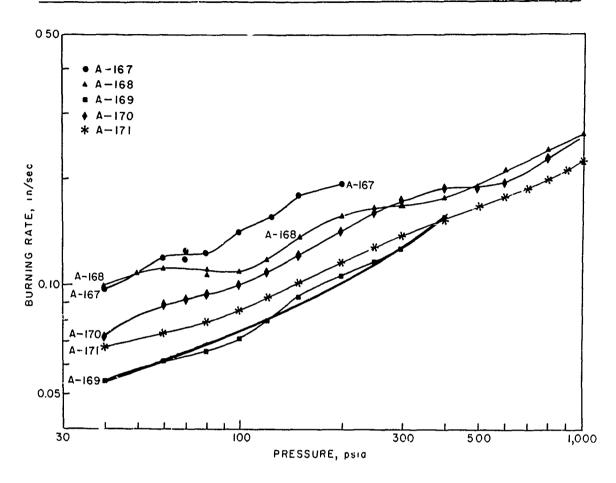

FIG. 2.12. Burning Rate Curves for Carboxy-terminated Pclybutadiene-ammonium Perchlorate Propellants.

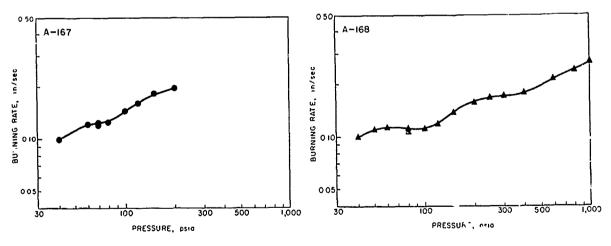

FIG. 2.13. Burning Rate Curve for Propellant A-167.

FIG. 2.14. Burning Rate Curve for Propellant A-163.

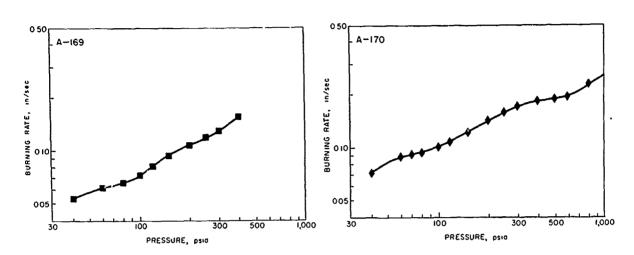

FIG. 2.15. Burning Rate Curve for Propellant A-169.

FIG. 2.16. Burning Rate Curve for Propellant A-170.

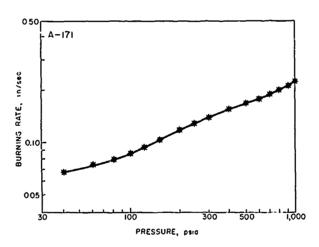

FIG. 2.17. Burning Rate Curve for Propellant A-171.

The type of binder also influences the shape of the burning-rate curve as seen when Fig. 2.2 and 2.12 are compared. The CTPB propellants do not exhibit the mesa characteristic and extinguishment behavior as did the polyurethane propellants. A simple slow heating rate test used by Steinz, et al. (Ref. 6) showed that polyurethane liquifies at low temperatures (T > 150°C) whereas CTPB gasifies without melting. Preliminary results indicate that the same behavior may also occur when the binders are subjected to the high heating rates which occur during combustion. Quenched samples of CTPB propellants will also be subjected to examination using the SEM; the object will be to ascertain if the propellant burns with a dry binder surface.

### 2.4 COMPARISON WITH ANALYTICAL MODELS

A number of analytical models have been proposed for steady-state burning of solid propellants (Ref. 5-7, see also references cited in Ref. 6). Of these, the granular diffusion flame (GDF) model of Summerfield, et al., (Ref. 8) seems to provide the best correlation of the ammonium perchlorate propellant data. Although the model is not developed from a fundamental, analytical representation of the three dimensional details of the combustion zone (no conservation laws are used), its authors claim to have originated the correct physical-chemical model (Ref. 6) which correlates most of the experimental burning rate data. These claims have been progressively qualified by recognition that the model only applies to a certain range of propellant formulations (referred to as "normal" propellants). By such a definition of normalcy, many in-service propellants have been excluded from the class of "normal" propellants for processing characteristics such as: (1) a relatively high fuel to oxidizer ratio, (2) a coarse oxidizer particle size (d > 250 microns). (3) a "meltable" binder. The burning rates of propellants which have a bimodal oxidizer particle size distribution (discussed below) indicate that the GDF model also does not adequately represent the effect of oxidizer particle size distribution.

The GDF model predicts that the burning rate will be related to pressure according to the expression  $p/r = a + bp^{2/3}$ , where a is a function primarily of thermochemical properties of the propellant and b is primarily a function of oxidizer particle size. This expression predicts that plots of p/r vs  $p^{2/3}$  will be straight lines, with a single value of the intercept a for a given chemical composition of propellant. Thus the plots of data for any series of propellants having equal amounts of identical binder, the same percent of ammonium perchlorate, and equal amounts of identical additives, should be a series of straight lines, which may have different slopes but which have the same p/r intercept. Results of the present studies are replotted in Fig. 2.18 and 2.19 as p/r vs  $p^{2/3}$ .

The results in Fig. 2.18 for the polyurethane propellants obviously are not in accord with the GDF model. Since the polyurethane binder is believed to melt at the burning surface, it would be classed by the authors of the GDF model as "abnormal," although it is in extensive use in service rockets. At the present time there seems to be no analytical model that correlates the behavior of these propellants.

The CTPB propellants used in this investigation conform to the currently stated definition of "normal" propellants for the GDF model, with the possible exception in one instance of an upper limit on oxidizer particle size (formulation A-169). The degree of correlation by the GDF model is much better than in the case of the polyurethane propellant, although the remaining discrepancies merit note. In particular, there are important (for the practical use of propellants) detailed deviations of the burning rate from the straight line p/r vs  $p^{2/3}$  correlation, which vary according to the combinations of coarse and fine AP in the bimodal mix.

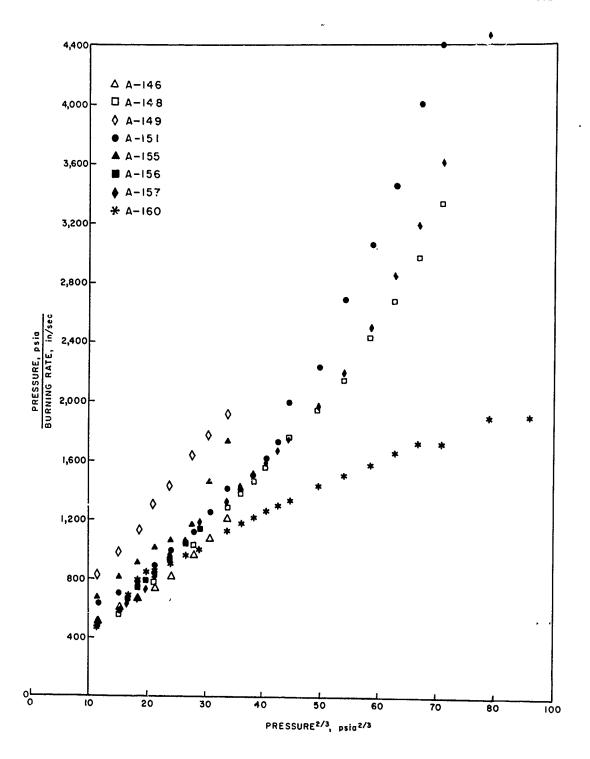

FIG. 2.18. Data from the Polyurethane-Ammonium Perchlorate Propellants Plotted in the Manner Suggested by the Granular Diffusion Flame Model Correlation.

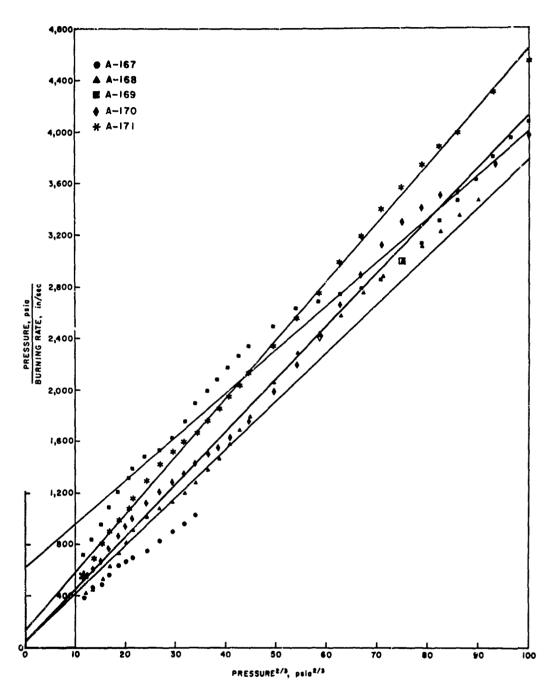

FIG. 2.19. Data from the Carboxy-Terminated Polybutadiene Propellants Plotted in the Manner Suggested by the Granular Diffusion Flame Model Correlation. The straight lines indicate a least square fit for data.

Values of a and b calculated from least squares fits to a straight line of the various sets of CTPB data are shown in the table below.

Propellant	8.	ъ
A-168	52.8	37.6
A <b>-</b> 169	622.1	34.0
A-170	58.8	40.8
A-171	131.6	45.2

As can be seen, there is considerable variation in the value of the intercept <u>a</u> as a function of particle size combinations (even when A-169 is excluded), even though <u>a</u> is supposed to depend only on chemical composition. The trend of the diffusion time parameter <u>b</u> does conform qualitatively to that predicted by the GDF model, although there is some ambiguity arising from proper definition of effective particle size relevant to this parameter.

### 2.5 CONCLUSIONS AND IMPLICATIONS FOR FUTURE WORK

- 1. Mesa burning rate curves and extinguishment at high pressures were observed with polyurethane binders, observations that may be of both practical and fundamental importance. This behavior may be due to a fluid nature of the binder at the burning surface, a point that will be explored further in future work by photographic and SEM techniques.
- 2. No analytical model accurately predicts the dependence of burning rate on pressure for the polyurethane-class of propellants.
- 3. The dependence of burning rate on pressure with the CTPB propellants was correlated roughly by the GDF model, but with some discrepancies of qualitative importance. The disagreement is related to the particle size distribution, an attribute of the propellant not embodied in existing analytical models.
- 4. In view of the complicated dependence of r on p observed in the present work, indiscriminate use of burning rate rules such as  $r=cp^n$  or  $r=a+bp^2/3$  is unwise. In particular, the use of  $r=cp^n$  in the several perturbation models for solid propellant combustion must lead to some misrepresentation of the pressure dependence of the response function.

### NONACOUSTIC COMBUSTION INSTABILITY

### 3.1 INTRODUCTION

The typical composite propellant is composed of a heterogeneous mixture of a solid oxidizer, polymeric fuel, and often a metallic additive. Because the mathematics involved in describing the combustion dynamics of such a heterogeneous mixture are quite complex, the assumptions of a one-dimensional combustion zone and a homogeneous solid are often made in order to make the problem tractable. This disregard for the heterogeneity of the propellant combustion zone is a valid assumption as long as the thermal-wave thickness is considerably larger than the individual ingredient size (i.e., oxidizer or fuel pocket size).

Since the thermal-wave thickness is often of the same order as the individual ingredient sizes for conventional composite propellants, it might be expected that the propellant heterogeneity could cause a noticeable deviation of experimental data from the one-dimensional theory. Therefore, a program was initiated to qualitatively assess what effects oxidizer particle size and binder type have on nonacoustic instability (NAI) behavior. Two series of propellants were formulated using ammonium perchlorate (AP) and either polyurethane (PU) or carboxy-terminated polybutadiene (CTPB) binder. The AP was carefully screened and the resulting 15-, 45-, 90-, 200-, 400- and 600-micron-diameter particles were mixed with the binders to produce the propellants described in Table 2.1. These propellants were fired in the L\*-burner at this Center. The data for the PU-AP propellants were presented in Ref. 1 and 2.

### 3.2 LAYER-FREQUENCY CONCEPT

A preliminary concept, called the layer-frequency concept, was also described in Ref. 1 and 2. This layer-frequency concept pictured a propellant as layers of oxidizer particles stacked one on top of another and surrounded by binder. The characteristic time to burn through an oxidizer particle would be the diameter of the particle divided by the mean burning rate, i.e.  $\tau = D/r$ ; this time would be repeated at a frequency of one cycle per particle within the stack. These minute pulsations, if in phase with one another over a part of the burning surface, could produce pressure oscillations having a frequency of  $f = 1/\tau = r/D$ .

The data presented in Ref. 1 and 2 indicated that when the thermal-wave thickness was on the order of the oxidizer particle size the one-dimensional analysis did not agree with the instability observed. Instead the data tended toward the higher frequencies as indicated by the layer-frequency concept. The concept of the layer frequency was also strengthened when two frequencies for the same run were observed as would be expected for propellants having a bimodal blend of oxidizer particle sizes. The layer-frequency computational scheme did therefore provide some insight into NAI.

### 3.3 RECENT EXPERIMENTAL RESULTS

The data obtained with the CTPB-AP propellants are presented in this section. Before discussing these data a few qualitative remarks comparing the oscillatory behavior of the PU-AP and the CTPB-AP propellants should be made. The CTPB-AP propellants produced more severe oscillations than did the propellants having the polyurethane binder; i.e., the amplitude of oscillations was greater for the CTPB propellants. Not only were the oscillations more severe but they were also "cleaner" and of longer duration, which made the determination of growth constants (Appendix A) less subject to errors.

From the discussions in Ref. 1 and 2 the greatest departure from one-dimensional theory would be expected at high values of burning rate (smaller thermal-wave thickness) and for large oxidizer particle sizes. This general trend with burning rate is illustrated by the data plotted in Fig. 3.1 and tabulated in Appendix A. The shaded parabolic band represents the predictions of one-dimensional theory; it is at the higher values of burning rate, r > 0.11 in/sec, that the data deviate most significantly from this band. At the lower values of burning rate the experimental data agree moderately well with the predictions of one-dimensional analysis.

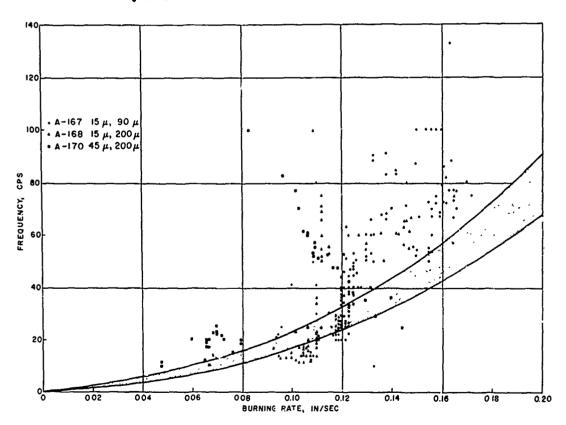

FIG. 3.1. Nonacoustic Combustion Instability Data for Three Carboxy-Terminated Polybutadiene-Ammonium Perchlorate Propellants.

Figure 3.2 presents the data for propellant A-167 which had 15- and 90-micron exidizer particles. The most significant deviation from the one-dimensional analysis occurs for burning rates above 0.12 in/sec; the thermal-wave thickness for this rate is approximately 32 microns.

Propellant A-168 (Fig. 3.3) with 15- and 200-micron particles deviates from the parabolic band for rates above 0.11 in/sec; the corresponding thermal-wave thickness is 40 microns. Also, propellant A-170 (Fig. 3.4) with 45- and 200-micron particles also deviates from the parabolic band for rates above 0.08 in/sec with a corresponding thermal-wave thickness of 55 microns.

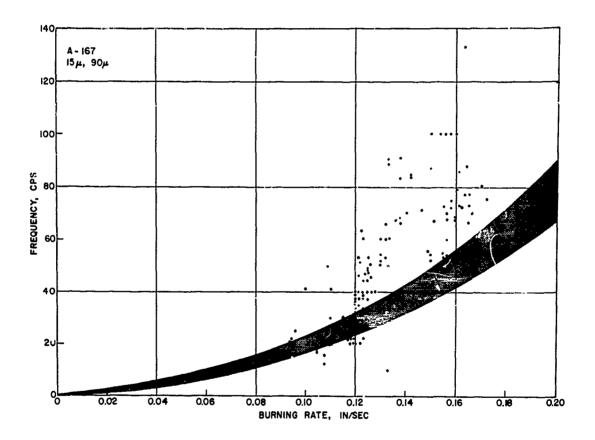

FIG. 3.2. Nonacoustic Combustion Instability Data for Propellant A-167.

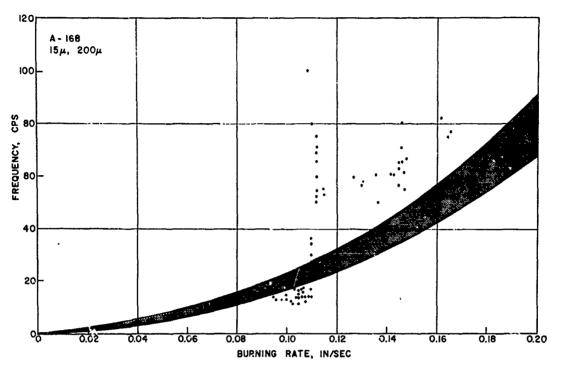

FIG. 3.3. Nonacoustic Combustion Instability Data for Propellant A-168.

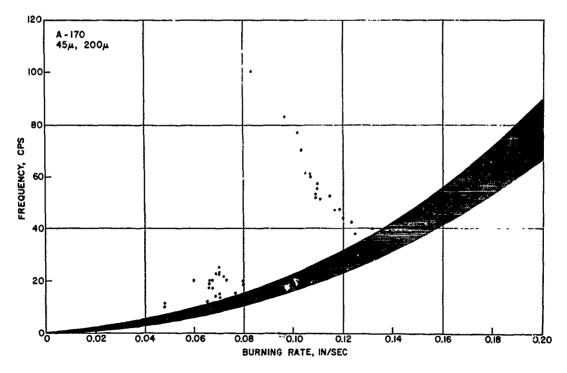

FIG. 3.4. Nonacoustic Combustion Instability Data for Propellant A-170.

### 3.4. SUMMARY AND IMPLICATIONS FOR FUTURE WORK

The results of this study indicate that one-dimensional analyses cannot be applied indiscriminately to combustion instability in the low-frequency regime (f  $\sim$  200 cps and lower). When conditions are such that the thermal-wave thickness is approximately equal to oxidizer particle size, the physical size of the oxidizer is a contributing (and possibly a dominating) factor of combustion instability. How this interaction of the thermal wave and oxidizer affects the response function of the propellant is presently being assessed. The simple layer-frequency concept also appears to be inadequate.

Additional L\* tests are being run with other CTPB-AP propellants. It is hoped that future data together with data already gathered will provide a basis for a more rigorous analysis to be made.

### 4. ACOUSTIC COMBUSTION INSTABILITY

In describing the transient processes involved in unstable combustion, various assumptions regarding combustion and flow behavior are made to simplify discussion and mathematical modeling. The most common assumption is that the combustion zone is thin compared to the wave length of the acoustic disturbance. A more stringent assumption is that the transit time through the combustion zone is long compared to a period of oscillation. While this latter assumption has been widely used in combustion perturbation theory, it is clearly violated at frequencies below a few hundred cycles per second. Some recent analytical and experimental studies have been directed at evaluation of the implications of this question, partly to determine how much effect to expect on calculated values of combustion response functions, and partly to determine how well our "understanding" of the combustion conforms with the actual combustion process.

In the present studies, an analytical representation of the oscillatory flow field outside the combustion zone was set up and coded for computer. The analysis assumes that each element of gas behaves isentropically in the oscillatory flow field (no diffusion). The combustion zone is characterized as an oscillatory flow source with amplitude and phase oscillations being pressure amplitude-dependent boundary parameters. The frequency dependence of these parameters would have to be determined by combustion-zone modeling or experiment, but are treated as parameters in the computer program. The program provides for calculation of the oscillatory temperature field and streak lines in the region above the combustion zone; comparison with experimentally measured streak pictures is shown in Fig. 4.1.

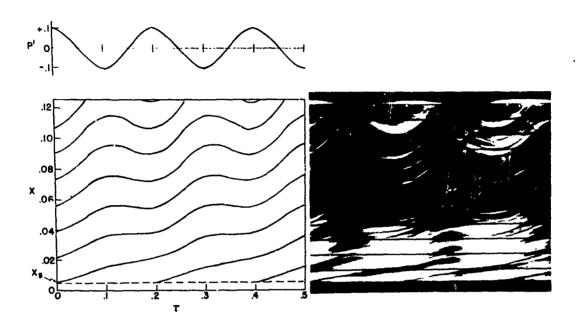

FIG. 4.1. Comparison Between Computed Trajectories and Actual Test Data. Both portions of the figure are on the same scale. Coordinates of the computed part are in dimensionless units of distance from the burning surface (x) and time (t). Evenly spaced lines on the streak film are one inch apart on the burner and the length of the film represents 20 milliseconds. The relationship of the acoustic pressure to particle trajectories is illustrated separately in the case of the computed results, while the acoustic pressure appears as a light line on the photographic record. Computed trajectories are for particles which left the burning surface when the acoustic pressure is a maximum. All trajectories start from a reference plane, designated  $x_s$  in the figure. (From Test No. 5114 at 4.00 seconds. Mean pressure is 74 psia, acoustic pressure amplitude is 15 psi p-p, burner length 100.5 inches, frequency 125 cms. Propellant contains 25% polyurethane binder, 0.04% NaCl, remainder is 80µ spherical ammonium perchlorate.)

The equations to be solved are expressed in nondimensional variables. They are:

$$p' = \varepsilon_p \cos(n\pi x) \cos(n\pi t + \psi)$$
 (4.1)

$$T_s^* = \frac{\gamma-1}{\gamma} \epsilon_p \epsilon_T \cos(n\pi x_s) \cos(\psi + \beta)$$
 ('.2)

$$T_g^* = \frac{\gamma - 1}{\gamma} \epsilon_p \{\cos (n\pi x) \cos (n\pi t + \psi) - \cos (n\pi x_g) \cos \psi\} \quad (4.3)$$

where p' is the instantaneous acoustic pressure, T' is the fluctuation of the gas temperature at a reference plane which is a distance x from the propellant, T' is the fluctuation of the gas temperature due to acoustic pumping, x is the displacement from the propellant surface,  $\psi$  is the phase of the acoustic pressure at the time of emergence of a particle,  $\beta$  is the phase between pressure and reference plane temperature,  $\epsilon$  is the amplitude of the pressure fluctuation, and  $\epsilon_m$  is a measure of the isentropicity of the temperature-pressure relationship at x ( $\epsilon_T$  = 1 if isentropic, = 0 if isothermal).

The gas temperature fluctuation at any point in the flow is given by

$$T^{\dagger} = T^{\dagger} + T^{\dagger}_{g} \tag{4.4}$$

The above equations involve a space variable "x" and a time variable "t" which are related by the following equation:

$$\frac{dx}{dt} = \overline{M} + \frac{\varepsilon_p}{\gamma} \sin (n\pi x) \sin (n\pi t + \psi) \qquad (4.5)$$

where  $\overline{M}$  is the dimensionless mean gas velocity. Solution of Eq. 4.5 provides the trajectory of a gas particle leaving the propellant surface and also takes acoustic flow perturbations into account.

An outline of the digital computer program used to solve the above set of equations appears in Appendix B. Eight dimensionless input parameters, derived from conditions prevailing at a particular time during an experiment, are required for a set of solutions. Output data are in the form of dimensionless parameters such as displacement of a gas element, the acoustic pressure, temperature at the reference plane, gas temperature and total temperature as functions of time and phase of emergence of the gas element. A portion of a typical computer solution appears in Appendix C.

Comparison between computed trajectories and experimental data has been made at several test conditions in the 5.5-inch diameter T-burner. Gas motion in the burner was recorded using the special test section containing a slit window and the streak camera in an experimental arrangement that has been previously described (Ref. 2). Figure 4.1 shows a comparison between computed results and streak camera data. The two portions of the figure are on the same scale. Comparison of the computed trajectory with the experimental data indicates that the model describes gas motion in the burner with reasonable accuracy.

The next phase of this study is to determine the oscillatory temperature field and compare it with calculated fields. Ideally, the analytical aspects of this effort would be accomplished by combining the flow field analysis with a model of the combustion zone behavior, as was attempted in Ref. 10. However, preliminary results suggest that available models of the combustion zone dynamics are not realistic enough to provide argument with the experiments, and future work will involve an interlocked development of theory and diagnostic experiments designed to identify the requirements for a realistic analytical model. Temperature measurements will be made in the flow field and will be compared with temperature predicted for various models of the combustion zone to determine which seems most applicable.

## Appendix C

## SAMPLE OF TYPICAL COMPUTER OUTPUT

A portion of typical computer output data from the particle trajectory, gas temperature program appears below. Parameter values are identical to those in Fig. 4.1. The output data

presented here were calcutic pressure maximum ( $\psi=0$ with the other data, has this case, $T_S=0.020397$ ,	late ). been	a gas ferenced	d for a gas particle which left the reference plane at an acoustine reference plane temperature, normally printed in a column omitted since $T_S$ has a fixed value for each value of $\psi$ . In	plane at an acousted in a column

## INSTRUCTIONS

- 1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.
- 20 REPORT SECURITY CLASSIFICATION. Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance wil' appropriate security regulations.
- 2b Gr. Automatic downgrading is specified in DoD Directive 10 and Armed Forces Industrial Manual. Enter the group mber. Also, wher applicable, show that optional marks of have been used for Group 3 and Group 4 as authorized.
- 4. DESCRIPTIVe: "ES: If appropriate, enter the type of report, e.g., interim, p. ogress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.
- 5. AUTHOR(S) Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.
- 6 REPORT DATE. Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.
- 7a. TOTAL NUMBER OF PAGES The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.
- 7b NUMBER OF REFERENCY, Enter the total number of references cited in the report
- 8a CONTRACT OR GRAN' NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.
- 8b, &c. & 8d. PROJECT NU. IBER: Enter the appropriate military department identification, such as project number, subproject number, system num, ers, task number, etc.
- 9a ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.
- 96 OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or b) the sponsor), also enter this number(s).
- 10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those

imposed by security classification, using standard statements such as:

- (1) "Qualified requesters may obtain copies of this report from DDC."
- (2) "Foreign announcement and dissemination of this report by DDC is not authorized."
- (3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through
- (4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through
- (5) "All distribution of this report is controlled. Qualified DDC users shall request through

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

- 11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.
- 12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and "evelopment. Include address."
- 13 ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C) or (U)

There is no limitation on the length of the abstract However, the suggested length is from 150 to 225 words

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, roles, and weights is optional
